Ionization of gold (γ-methoxy)vinyl complexes generates reactive gold vinyl carbene complexes†

Nana Kim and Ross A. Widenhoefer*  

Cationic gold vinyl carbene/allylic cation complexes of the form (E)-[(L)AuC(H)C(H)CAr2]2+ OTf− (L = IPr, Ar = Ph [(E)-5a], L = IPr, Ar = 4-C6H4OMe [(E)-5b], L = P(t-Bu)2-biphenyl, Ar = 4-C6H4OMe [(E)-5c]) were generated in solution via Lewis acid-mediated ionization of the corresponding gold (γ-methoxy)vinyl complexes (E)-(L)AuC(H)C(H)C(OMe)Ar2 at or below −95 °C. Complexes (E)-5b and (E)-5c were fully characterized in solution employing multinuclear NMR spectroscopy, which established the predominant contribution of the aurated allylic cation resonance structure and the significant distribution of positive charge into the γ-anisyl rings. Complex (E)-5b reacted rapidly at −95 °C with neutral two-electron, hydride, and oxygen atom donors exclusively at the C1 position of the vinyl carbene moiety and with p-methoxystyrene to form the corresponding vinylcyclopropane. In the absence of nucleophile (E)-5a decomposed predominantly via intermolecular carbene dimerization whereas formation of 1-aryl-5-methoxy indene upon ionization of (Z)-(IPr)AuC(H)C(H)C(OMe)(4-C6H4OMe)2 [(Z)-6b] implicated an intramolecular Friedel–Crafts or electrocyclic Nazarov pathway for the decomposition of the unobserved vinyl carbene complex (Z)-(IPr)AuC(H)C(H)C(4-C6H4OMe)1+ OTf− [(Z)-5b].

Introduction

Cationic gold carbene complexes have been invoked as intermediates in a diverse range of gold(I)-catalyzed transformations1–3 and, for this reason, considerable effort has been directed toward understanding the structure and reactivity of these complexes.4 A particularly important subset of the reactive gold carbene complexes is the gold vinyl carbene/allylic cation complexes, with the potential for both the delocalization of positive charge on the Au, C1, and/or C3 atoms and diverse reaction pathways (Fig. 1). Cationic gold carbene complexes have been invoked as intermediates in range of gold-catalyzed transformations employing cyclopropenes,5–8 propargyl carboxylates,9,10 propargyl ethers,11 enynes,12 ene-allenes,13 vinyl diazo compounds,14 and norcaradienes as vinyl carbene precursors.15

Notwithstanding the insight provided through the computational analysis of Toste and Goddard,16 information regarding the structure and reactivity of cationic gold vinyl carbene complexes is scarce, owing in large part to the absence of suitable model complexes for interrogation.4 Only three cationic gold vinyl carbene/allylic cation complexes (1–3) have been characterized, each of which contains either a C1 or multiple C3 oxygen atoms (Fig. 2).17–18 As such, neither the electronic structure nor reactivity of complexes 1–3 is likely to mimic that of the reactive vinyl carbones generated under gold(I) catalysis.3,1–5 Indeed, well defined, two-coordinate gold carbene complexes that display reactivity analogous to their catalytic counterparts, gold to alkene carbene transfer in

particular, are exceedingly rare. Although weakly-stabilized vinyl carbene complexes are known for a range of transition metals, the properties of cationic gold(Ⅰ), including high d-electron count, electronegativity and poor d→π back bonding, likely render the electronic structure and reactivity of cationic gold vinyl carbene complexes distinct from these related complexes.

We have recently reported the synthesis of the cationic, two-coordinate gold(Ⅰ) diphenylallenylidene complex 4 and related complexes, generated via the Lewis acid-mediated ionization of the corresponding gold (γ-methoxy)acetylide complexes (Scheme 1), and which represent rare examples of cationic gold carbene complexes lacking π-conjugated heteroatoms. The efficiency and facility of the γ-ionization process suggested that a similar approach might provide access to particularly reactive gold vinyl carbene/allylic cation complexes. Indeed, here we report that ionization of gold (γ-methoxyγ-γ-diaryl)vinyl carbene complexes generates cationic, two-coordinate gold vinyl carbene complexes that react rapidly at −95 °C with a range of nucleophiles, including alkenes, and that decompose in the absence of nucleophile via inter- or intramolecular pathways. The spectroscopy of these complexes points to strong contribution of the aurated allylic cation resonance form and stabilization by the γ-aryl groups.

Results and discussion

Guided by our investigation of cationic gold allenylidene complexes, we targeted the gold γ,γ-(diphenyl)vinylcarbene/allylic cation complex (E)-[(IPr)AuC(H)C(H)CPh2] OTf (E)-5a for initial investigation (Scheme 2). The requisite gold (γ,γ-diphenyl)vinyl complex (E)-(IPr)AuC(H)C(H)C(OMe)Ph2 [E]-6a was synthesized in two steps from propargylic ether 7a via zirconium-catalyzed hydroboration followed by transmetalation of the resulting boronic ester (E)-8a with (IPr)AuCl (Scheme 2). Treatment of (E)-6a with trimethylsilyl trifluoromethanesulfonate (TMSOTf) in CD2Cl2 at −95 °C led to immediate (<1 min) formation of a bright orange/red solution that became colorless over the course of ∼10 s. 1H NMR analysis of the resulting solution at −95 °C revealed formation of trimethylsilyl methyl ether (TMSOMe) in 92 ± 5% yield, which established that efficient ionization of (E)-6a had occurred, but no resonances were observed that could be attributed to (E)-5a. Rather 1H NMR analysis revealed formation of a ∼11 : 1 mixture of (E)- and (Z)-1,1,6,6-tetraphenylhexa-1,3,5-triene in 70% combined yield, presumably generated via homocoupling of the vinyl carbene groups of (E)-5a (Scheme 2). In an effort to directly observe vinyl carbene (E)-5a, a solution of (E)-6a was treated with TMSOTf at −110 °C in CDFCl2/CD2Cl2 and analysed immediately by 1H NMR spectroscopy. The resulting spectrum was broadened and largely uninterpretable, but displayed a pair of mutually-coupled doublets at δ 10.83 and 8.18 (J = 17.5 Hz), assigned to the C1 and C2 vinylic protons, respectively, of (E)-5a (Table 1).

(E)-5a — −110 °C in CDFCl2/CD2Cl2, (E)-5b — −95 °C in CD2Cl2, (E)-5c −90 °C in CD2Cl2.

Scheme 1 Synthesis of gold allenylidene complex 4 [(IPr)Au=C=C=C=C=Cl].

Scheme 2 Synthesis and thermal decomposition of gold vinyl carbene/allylic cation complex (E)-5a.
In an effort to enhance the stability of the gold vinyl carbene/allylic cation complex to allow more rigorous spectroscopic interrogation and reactivity analysis, we turned our attention to the gold \(^{\gamma,\gamma}\)-bis(anisyl)vinyl carbene/allylic cation complex \((E)-[(\text{IPr})\text{AuC(H)}\text{C(H)}\text{C}(4-C_{6}H_{4}OMe)_{2}]^+\text{OTF}^-\) \((E)-5b\). To this end, ionization of gold vinyl complex \((E)-6b\) in CDCl\(_3\) at \(-95^\circ\text{C}\) led to immediate (<1 min) formation of the bright red-orange solution of \((E)-5b\) in 96 ± 5% yield \((1^H\text{NMR})\), which persisted indefinitely at this temperature (Scheme 3). In a similar manner, ionization of the phosphine-supported gold vinyl complex \((E)-6c\) at \(-95^\circ\text{C}\) led to formation of \((E)-5c\) in 95% yield \((1^H\text{NMR};\text{Scheme}\ 3)\), which darkened noticeably over the course of several hours at \(-95^\circ\text{C}\).

Complexes \((E)-5b\) and \((E)-5c\) were fully characterized by NMR spectroscopy at or below \(-85^\circ\text{C}\) (Table 1). For example, the \(^{13}\text{C}\) NMR spectrum of \((E)-5b\) displayed downfield resonances at \(\delta\ 243.7, 146.9,\) and 185.7 assigned to the C1, C2, and C3 carbon atoms, respectively, of the vinyl carbene/allylic cation moiety. These resonances as well as \(^{13}\text{C}\) NMR analysis of the corresponding \(^{13}\text{C}\)-labelled isotopomer \((E)-[(\text{IPr})\text{Au}^{13}\text{C(H)}\text{C(H)}\text{C}(4-C_{6}H_{4}OMe)_{2}]^+\text{OTF}^-\) \((E)-5b^{13}\text{C}_{2}\). The \(^{13}\text{C}\) NMR spectrum of \((E)-5b\) also displayed a pair of downfield resonances at \(\delta\ 168.3\) and 167.6 assigned to the chemically inequivalent methoxy-bound aromatic carbon atoms. These resonances were shifted significantly downfield relative to those of neutral \((E)-6b\) (\(\delta\ 140\)), which points to the significant delocalization of positive charge onto the \(\gamma\)-anisyl rings of \((E)-5b\).

The \(^1\text{H}\) NMR spectrum of \((E)-5b\) at \(-95^\circ\text{C}\) displayed two mutually-coupled doublets at \(\delta\ 9.51\) and 7.71 \((J = 17.8\ \text{Hz})\) assigned to the C1 and C2 protons, respectively, and a pair of singlets at \(\delta\ 3.89\) and 3.96 assigned to the chemically inequivalent aryl methoxy protons. As the temperature was raised, the methoxy resonances broadened and coalesced at \(-42^\circ\text{C}\), albeit with significant decomposition, which provided an energy barrier of \(DG^{231K} = 10.5\ \text{kcal/mol}^{-1}\) for interconversion of the anisyl groups of \((E)-5b\) (Fig. 3). Both the facile rotation about the C2–C3 bond of \((E)-5b\) and the significant delocalization of positive charge onto the \(\gamma\)-anisyl rings of \((E)-5b\) point to the predominant contribution resonance structures D to the electronic structure of \((E)-5b\) (Fig. 4), which is likewise consistent with the significantly greater thermal stability of \((E)-5b\) relative to \((E)-5a\).

Warming a solution of \((E)-5b\) at \(-40^\circ\text{C}\) \((t_{1/2} = 35\ \text{min})\) or \((E)-5c\) at \(-60^\circ\text{C}\) \((t_{1/2} = 10\ \text{min})\) led to decomposition to form unidentified mixtures of products that included neither the products of intramolecular Friedel–Crafts alkylation nor carbene dimerization as determined by GCMS and LCMS analysis. We were somewhat surprised by the absence of Friedel–Crafts/Nazarov reactivity for complexes \((E)-5\), which is well documented for 1-aryl allylic cations\(^{31,32}\) and which is directly implicated in the gold(I)-catalyzed ring-opening of aryl cyclopropenes.\(^{5,6}\) We reasoned that the less stable gold Z-vinyl carbene complexes, which are generated as the kinetic products of cyclopropene ring opening,\(^{33}\) might be more susceptible toward intramolecular cyclization processes than are the E-vinyl carbene complexes. To evaluate this hypothesis, we sought the independent synthesis of vinyl carbene complex \((Z)-5b\). To this

end, the gold vinyl complex (Z)-6b was synthesized in two steps from propargyl ether 7b via rhodium-catalyzed, anti-selective hydroboration\(^\text{14}\) followed by transmetallation of boronic ester (Z)-8b (Scheme 4).

Ionization of (Z)-6b with TMSOTf at \(-95^\circ\text{C}\) formed a pale orange solution that displayed no resonances in the \(^1\text{H}\) NMR spectrum that could be attributed to vinyl carbene complex (Z)-5b.\(^\text{8}\) Rather, warming this solution above \(-50^\circ\text{C}\) led to formation of the 1-aryl-5-methoxy indene \(9\) in 58% yield (\(^1\text{H}\) NMR; Scheme 4). Because 1-aryl indenes are less stable than are the isomeric 3-aryl indenes,\(^\text{19}\) \(9\) must be formed kinetically, which points to a mechanism for the conversion of (Z)-5b to \(9\) involving intramolecular Friedel–Crafts alkylation or electrocyclic Nazarov-type cyclization followed by selective protonation of the \(\gamma\)-position of gold allyl intermediate \(11\) through an \(S_{\text{p}}\)' pathway (Scheme 5). Interestingly, (3-phenyl-1,1-dimethoxy-inden-1-yl)gold(i) complexes very similar to intermediate \(11\) have been recently isolated via thermal rearrangement of neutral (3,3-diphenylcyclopenta-1,4-dien-1-yl)gold(i) complexes and were shown to undergo protodeauration with HCl predominantly through an \(S_{\text{p}}\)' pathway.\(^\text{36,37}\) The facility of the intramolecular Friedel–Crafts/Nazarov reaction of (Z)-5b and the failure to form \(9\) in the decomposition of (E)-5b therefore suggests that the energy barrier for E/Z isomerization of (E)-5b exceeds that of the lowest energy decomposition pathway available to (E)-5b (\(\Delta G^\ddagger = 16\) kcal mol\(^{-1}\)).

Nucleophilic trapping of a cationic gold vinyl carbene complex represents one of the most terminating steps of catalytic transformations involving these intermediates.\(^\text{5,7,8}\)

In a similar manner, treatment of (E)-5b with either tetrahydrothiophene (THT) or pyridine at \(-95^\circ\text{C}\) in CD\(_2\)Cl\(_2\) led to immediate (<1 min) disappearance of the distinctive red color to form pale yellow solutions of the gold allyl carbene complexes \(10\) and \(11\), respectively, in >90% yield (\(^1\text{H}\) NMR; Scheme 6). These complexes were characterized in solution, and in the case of \(11\), by X-ray crystallography (Fig. 5). For example, selective attack of THT at the C1 vinyl carbene carbon atom of (E)-5b was established by a pair of mutually-coupled doublets at \(\delta\) 3.22 and 5.60 \((J = 11.5\) Hz) assigned to the aliphatic C1 and vinyl C2 protons, respectively of \(10\). In the solid state, \(11\) adopts a slightly distorted linear conformation (C1–Au–C28 = 177°) with the C1 allylic carbon atom adopting a distorted sp\(^3\) geometry with a larger Au–C28–C29 angle (115°) and smaller Au–C28–N3 and N3–C28–C29 angles (108°) (Fig. 5). Treatment of \(10\) (15 mM) with pyridine (1 equiv.) at 0 \(^\circ\text{C}\) for 2 h led to formation of an equilibrium 1.25 : 1 mixture of \(11 : 10\) \((K_{\text{eq}} = 1.8 \pm 0.1\); Scheme 6). Kinetic analysis of the conversion of \(10\) to \(11\) established first-order approach to equilibrium through 2.5 half-lives with forward and reverse rate constants \(k_1 = 4.1 \pm 0.9 \times 10^{-4}\) s\(^{-1}\) and \(k_2 = 2.3 \pm 0.5 \times 10^{-4}\) s\(^{-1}\). The first-order kinetic behaviour points to a dissociative mechanism for the interconversion of \(10\) and \(11\) involving free (E)-5b.

Oxygen atom transfer to the C1 position of a gold vinyl carbene intermediate has been invoked in the gold-catalyzed reactions of cyclopropenes with diphenylsulfoxide.\(^\text{7,38,39}\) In a similar manner, treatment of (E)-5b with 4-picoline N-oxide (4-}

One of two crystallographically independent molecules is depicted with ellipsoids shown at the 50% probability level with counterion and hydrogen atoms omitted for clarity. Selected bond distances (Å) and bond angles (deg) for \(11\): Au–C1 = 2.005(4), Au–C28 = 2.067(5), C28–C29 = 1.495(5), C29–C30 = 1.343(7), C28–N3 = 1.515(6), C30–C36 = 1.501(8), C30–C43 = 1.55(1), C1–Au–C28 = 177.4(2), Au–C28–C29 = 115.6(3), Au–C28–N3 = 107.8(3), N3–C28–C29 = 108.3(4), C28–C29–C30 = 125.5(5), C29–C30–C43 = 126.1(9), C29–C30–C36 = 121.6(5), C36–C30–C43 = 112.0(9).
PNO) (1.9 equiv.) in CD$_2$Cl$_2$ at −95 °C for ~1 min led to formation of 3-aryl-cinnamaldehyde 12 in 88% yield and the 4-picoline gold complex [(IPr)Au(4-pic)]$^+$ OTf$^-$ in quantitative yield (Scheme 7). This outcome is consistent with selective oxygen atom transfer to the C1 carbon atom of the vinyl carbene moiety of (E)-5b followed by elimination from the unobserved α-oxopyridinium intermediate III. Related to this, treatment of (E)-5b with triethylsilane at −95 °C led to immediate (<1 min) and selective formation of the cationic gold π-allyl silane complex 13, presumably via hydride addition to the C1 position of (E)-5b followed by silyldeauration of the resulting gold allyl intermediate through an S$_g$ pathway. Warming this solution above −40 °C led to decomplexation and formation of allylic silane 14 in quantitative yield. Both the reaction of (E)-5b with DSiEt$_3$ and the reaction of the deuterated isotopomer (E)-5b-d$_1$ with HSiEt$_3$ at −95 °C led selective incorporation of deuterium into the allylic position to form 13-d$_1$ as a ~1 : 1 mixture of diastereomeric isotopomers, pointing to a stepwise deauration/complexation process (Scheme 8).

Despite the dearth of examples of stoichiometric gold to alkene carbene transfer,$^{19,20}$ perhaps no process is more closely associated with the reactive gold carbene complexes, including vinyl carbene complexes, generated as catalytic intermediates.$^{1,13}$ It is therefore significant that vinyl carbene complex (E)-5b underwent facile gold to alkene carbene transfer with p-methoxystyrene. For example, treatment of (E)-5b with p-methoxystyrene (3 equiv.) at −95 °C led to immediate (<3 min) consumption of (E)-5b to form the gold π-vinyl cyclopropane complex 15 (Scheme 9). Although $^1$H NMR analysis of this solution at −95 °C was complicated by the presence of free p-methoxystyrene and byproducts, a doublet was observed at δ 4.99 (J = 10.2 Hz), assigned to the vinyl proton of 15, which corresponded to a 75% yield of 15 from (E)-5b (Scheme 9). Warming this solution of 15 above −40 °C led to decomplexation to form free vinyl cyclopropane 16 in 67% NMR yield from (E)-5b as a ~3 : 1 mixture of cis/trans isomers (Scheme 9). Assignment of the δ 4.99 resonance to the vinyl proton of 15 was confirmed by independent synthesis of 15 from reaction of 16 (cis/trans = 3 : 1) with a mixture of [IPr]AuCl and AgSbF$_6$ in CD$_2$Cl$_2$ at −80 °C.$^{6}$

**Conclusions**

We have generated highly reactive gold vinyl carbene/allylic cation complexes via low-temperature ionization of gold γ-methoxy-γ,γ-diaryl vinyl complexes. Spectroscopic analysis of vinyl carbene/allylic cation complex (E)-5b established the predominant contribution of the aurated allylic cation canonical form to the electronic structure of the vinyl carbene complex (C; Fig. 1) with significant delocalization of positive charge into the γ-anisyl groups. Indeed, the significantly greater stability of the γ,γ-bis(anisyl) vinyl carbene complex (E)-5b relative to the γ,γ-diphenyl vinyl carbene complex (E)-5a points to the importance of the p-methoxy groups in the stabilization of (E)-5b.$^{41}$ Complex (E)-5b reacted rapidly at −95 °C with neutral two-electron, hydride, and oxygen atom donors exclusively at the C1 position of the vinyl carbene/allylic cation moiety and with p-methoxystyrene to form vinyl cyclopropane. These transformations are close or direct analogues to processes attributed to gold vinyl carbene intermediates generated under catalytic conditions.$^{1,15,33}$ Two distinct pathways for decomposition of these gold vinyl carbene complexes in the absence of nucleophile were identified; complex (E)-5a decomposed predominantly via intermolecular carbene
