Grainyhead-like 2 inhibits the coactivator p300, suppressing tubulogenesis and the epithelial–mesenchymal transition

Phillip M. Pifer, Joshua C. Farris, Alyssa L. Thomas, Peter Stoilov, James Denvir, David M. Smith, and Steven M. Frisch

INTRODUCTION

The protein p300 is a coactivator of transcription that interacts with at least 400 DNA factors to activate transcription from thousands of enhancers/promoters, mostly contingent upon its intrinsic histone acetyltransferase (HAT) activity. In this context, it is viewed as an “integrator” factor that serves as a nexus among multiple signaling pathways and programs of gene expression (Kamei et al., 1996; Vo and Goodman, 2001; Bedford et al., 2010; Yao et al., 2013). Accordingly, p300/CREB-binding protein (CBP)–null mice die at embryonic days 9.5−11.5 with massive deficits of mesenchymal cells and erythroid cells, as well as with defects in neurulation and heart development (Oike et al., 1999; Yao et al., 2013). p300 is essential for the differentiation of muscle, erythroid lineages, osteoblast, oligodendrocytes, and stem cells (Puri et al., 1997; Oike et al., 1999; Blobel, 2000; Polesskaya et al., 2001; Narayanan et al., 2004; Teo and Kahn, 2010; Zhang et al., 2016). A recent study showed that p300 is a marker for superenhancers, positioning it to control cell state transitions (Witte et al., 2015).

Grainyhead-like 2 (GRHL2) is one of the three genes comprising a family of mammalian transcription factors related to Drosophila Grainyhead, the first zygotically encoded transcription factor expressed during the maternal-to-zygotic transition (Harrison et al., 2010). GRHL2 is important for epithelial barrier assembly in, for example, the morphogenesis of kidney collecting ducts, placenta, lung alveoli, and the mammary gland ductal system (through OVOL2, a GRHL2 target gene) (Gao et al., 2013; Watanabe et al., 2014;
Grainyhead-like factors are also critical for diverse developmental events that involve the formation of epithelial barriers, including epidermal assembly, neural crest formation, and, in the adult, wound healing (Wilanowski et al., 2002; Gustavsson et al., 2008; Wang and Samakovlis, 2012; Mlacki et al., 2015). GRHL2 activates the expression of multiple genes encoding epithelial cell adhesion molecules (e.g., E-cadherin, desmosomal proteins, tight junction proteins) and, due to its widespread expression, may be generally important for enforcing an epithelial phenotype (Wilanowski et al., 2002; Ting et al., 2003, 2005; A uden et al., 2006; Rifat et al., 2010; Werth et al., 2010; Boglev et al., 2011; Ciieply et al., 2012; Senga et al., 2012; Tanimizu and Mitaka, 2013; Aue et al., 2015). Correspondingly, GRHL2 expression plays an important role in suppressing the oncogenic EMT, thereby functioning as a tumor suppressor that enhances anoikis sensitivity (Ciieply et al., 2012, 2013; Mlacki et al., 2015); in fact, the gene most tightly correlated with E-cadherin expression is GRHL2 (Kohn et al., 2014).

The opposing roles of GRHL2 in establishing the epithelial state versus p300 in differentiation—including EMT—motivated us to investigate a potential role for GRHL2 in inhibiting p300 function. Kidney tubulogenesis is contingent upon temporal and spatial regulation of epithelial cells, in which GRHL2, which is expressed in the ureteric buds of the developing kidney, plays a critical organizing role (Schmidt-Ott et al., 2005; Aue et al., 2015; Walentin et al., 2015). Madin–Darby canine kidney (MDCK) tubulogenesis in response to hepatocyte growth factor (HGF) models some aspects of kidney collecting-duct tubulogenesis in vivo and requires a transient, partial EMT (Pollack et al., 1998, 2004; O’Brien et al., 2002; Leroy and Mostov, 2007; Hellman et al., 2008; Jung et al., 2012; Zhang et al., 2014). HGF causes MDCK cells to undergo cell scattering in two-dimensional culture and induces tubulogenesis of MDCK cysts that form in a three-dimensional collagen gel (Wang et al., 1990; Pollack et al., 2004). Induction of MMP1 and MMP13 by HGF through AP1/p300 complexes is required for tubulogenesis in the MDCK model (Benbow and Brinckerhoff, 1997; Clark et al., 2008; Hellman et al., 2008; Chacon-Heszele et al., 2014). Targeted knock-out studies indicate a role for HGF/Met in kidney development, and, relatedly, HGF/Met signaling is a potent stimulator of Wnt signaling, a crucial signaling pathway in this process, validating the in vivo relevance of this approach (Monga et al., 2002; Bridgewater et al., 2008; Ishibe et al., 2009).

Here we report that GRHL2 promoted cystogenesis but suppressed tubulogenesis. GRHL2 protein interacted functionally with p300, inhibiting its HAT activity and transcriptional activation of target genes, including matrix metalloproteases. A small (13 amino acids [aa]) sequence of GRHL2 was important for inhibition of p300, suppression of tubulogenesis, and reversal of EMT. These results mechanistically position GRHL2, an enforcer of the epithelial default phenotype, as an antagonist of p300, a coactivator of differentiation-specific genes, with important ramifications for developmental and tumor biology.

RESULTS

GRHL2 suppresses cell scattering and tubulogenesis

In light of the epithelial programming role of GRHL2, we tested the effect of HGF on GRHL2 levels in MDCK cells. We found that HGF down-regulated the expression of endogenous GRHL2 protein levels at early time points (Figure 1A). When constitutively expressed in MDCK cells, GRHL2 significantly inhibited HGF-induced cell scattering compared with vector control cells (Figure 1B). Conversely, MDCK cells with GRHL2 short hairpin RNA (shRNA) knockdown demonstrated enhanced HGF-induced cell scattering; retention of E-cadherin expression showed that EMT did not occur in response to the knockdown of GRHL2 alone (Figure 1C and Supplemental Figure S1 Video). GRHL2 had only modest effects on the phosphorylation status of two established HGF/Met signaling mediators, Erk and Akt (Supplemental Figure S2).

We then examined the effects of GRHL2 on HGF-induced tubulogenesis in the three-dimensional collagen model. GRHL2 expression caused the formation of larger cysts than in vector control cells, consistent with previous reports on hepatic bile duct cells (Figure 1D; Tanimizu and Mitaka, 2013). GRHL2 significantly suppressed tubulogenesis/branching morphogenesis after HGF treatment (Figure 1D); a similar effect of murine Grhl2 was observed in mouse inner medullary collecting-duct cell line (Supplemental Figure S3A), indicating the important role of GRHL2 down-regulation in tubulogenesis. Conversely, the stable knockdown of GRHL2 prevented cystogenesis (Supplemental Figure S3B), presumably by down-regulating epithelial adhesion molecules (Werth et al., 2010; Senga et al., 2012). Transient knockdown of GRHL2 after cyst formation using a doxycycline-induced shRNA vector, however, clearly indicated that the loss of GRHL2 promoted tubulogenesis (Supplemental Figure S4A). There was no effect of the GRHL2 shRNA on cell proliferation (Supplemental Figure S4B). These results indicated that GRHL2 suppressed HGF-activated cell scattering and tubulogenesis.

GRHL2 suppresses the expression of matrix metalloproteases

To identify GRHL2 target genes responsible for the attenuation of cellular responses to HGF/Met signaling, we used RNA-sequencing (RNA-Seq) to compare MDCK cells with constitutive GRHL2 expression versus GRHL2 depletion with either no treatment or HGF induction (24 h). This experimental scheme allowed for two distinct comparisons: genes regulated by HGF in the absence versus presence of GRHL2, and genes regulated by GRHL2 with versus without HGF induction. GRHL2 down-regulated several known matrix metalloprotease (MMP) family members (Table 1; confirmed by quantitative PCR [qPCR] in Figure 2A). In light of the established importance of specific MMPs for tubulogenesis in the MDCK and mMDCK-3 cell culture models (Rotary et al., 2000; Jorda et al., 2005; Hellman et al., 2008; Chacon-Heszele et al., 2014), we verified their importance for branching tubulogenesis in embryonic kidneys cultured ex vivo using the generalized MMP inhibitor batimastat (Supplemental Figure S5). The down-regulation of MMPs by GRHL2 contributed significantly to the tubulogenesis-suppressing effect of constitutive GRHL2 expression, although additional contributions from EMT/mesenchymal-epithelial transition (MET)—related GRHL2 genes are likely.

To investigate the transcriptional mechanisms of MMP gene regulation by GRHL2, we assayed MMP1 and MMP14 promoters as luciferase reporter constructs by cotransfection in HT1080 fibrosarcoma cells, in which the endogenous MMPs are expressed constitutively (Tang and Hemler, 2004; Nonaka et al., 2005). GRHL2 was found to suppress MMP1 and MMP14 promoters using adenovirus E1a protein, a known repressor of MMP genes, as a positive control (Figure 2B). These results demonstrate that GRHL2 repressed MMP1 and MMP14 promoters; however, examination of the promoter sequences used in our reporter constructs did not indicate the presence of GRHL2 DNA–binding consensus sites (Wilanowski et al., 2002; Gao et al., 2013; Aue et al., 2015; Walentin et al., 2015), suggesting a subtler mechanism for repression not involving direct DNA binding.
GRHL2 inhibits p300 function

The AP-1 transcription factor family is important in the regulation of most MMP genes (Clark et al., 2008). GRHL2 significantly suppressed AP-1 activity on minimal reporter constructs in HT1080 and 293 cells (Figure 3A). GRHL2 did not appear to affect the expression of FOS or JUN family members after HGF induction (Supplemental Figure S6).

In light of the functional similarities between adenovirus E1a and GRHL2 (see Discussion), we compared a published list of genes that E1a down-regulated through p300 interaction (Ferrari et al., 2014) against our list of GRHL2–down-regulated genes; the latter list was derived from the RNA-Seq analysis that we performed on GRHL2-expressing human mesenchymal subpopulation (MSP) cells (Farris et al., 2016) and used because a comparison of canine versus human gene lists proved uninformative for technical reasons. About 43.5% of the genes that E1a repressed through p300 were also repressed by GRHL2 (Figure 3B). Downstream Effector Analysis/Ingenuity Pathway Analysis revealed that the expression of GRHL2 suppressed the regulation of numerous p300-associated genes that were up-regulated or down-regulated by HGF in the absence of GRHL2 expression (Figure 3C and Supplemental Figure S7). These results suggested that GRHL2 could potentially inhibit p300 function.

To investigate this, we assayed the effect of GRHL2 on the activity of a GAL4-DNA binding domain–p300 fusion protein by transient transfection using a GAL4-responsive luciferase promoter, an established method for testing p300 coactivator function without confounding effects from primary DNA-binding activator proteins (Snowden et al., 2000). Adenovirus E1a protein repressed the AP-1 and GAL4/GAL4-p300 reporter activities, but a p300-nonbinding mutant of E1a (Ferrari et al., 2014) failed to do so (Supplemental Figure S8), validating the p300 dependence of transcription in these assays. GRHL2 inhibited the coactivator function of p300 in this assay (Figure 3D). As additional negative controls, GRHL2 did not affect the ability of a p300-independent GAL4-activator fusion protein (VP16-GAL4; Kutluay et al., 2009) to activate the same reporter; an other transcription factor unrelated to GRHL2, c-Myc, failed to inhibit GAL4-p300 function in this assay (Supplemental Figure S9). These results indicated that GRHL2 was a potent suppressor of p300 function. The highly related GRHL1 and GRHL3 proteins had similar effects in the reporter assay (Supplemental Figure S10).

GRHL2 inhibits the histone acetyltransferase activity of p300

The HAT domain of p300 acetylates numerous substrates, including lysines 18 and 27 in the N-terminal tail of histone 3 (H3; Ogryzko et al., 1996; Kasper et al., 2010; Jin et al., 2011). Using recombinant proteins, we found that GRHL2 inhibited acetylation of H3K27 by p300 in a dose-dependent way in vitro (Figure 4A). We found similar results using the p300 HAT domain alone (aa 1283–1673) rather than full-length p300 (Supplemental Figure S11). Recombinant GRHL1 and GRHL3 proteins also inhibited the HAT activity of p300 (Supplemental Figure S12).

To confirm these in vitro effects in cells, we analyzed histone acetylation by chromatin immunoprecipitation (CHIP)–qPCR using
the human cell line HT1080 (because Encode reference data reporting histone acetylation are available for the human genome). Consistent with the in vitro results, the acetylation of H3K27 was inhibited in HT1080 cells expressing GRHL2 constitutively, specifically on promoters that GRHL2 repressed, including MMP1, MMP14, MMP2, and ZEB1; acetylation of GRHL2-up-regulated gene promoter–associated H3K27 was either not affected (CDH1, ESRP1) or up-regulated (RAB25; Figure 4B). Unlike the effect of E1a on p300, there was neither an effect of GRHL2 on global H3 acetylation nor global chromatin condensation, as assayed by Western blotting (Figure 4B) or immunofluorescence localization of a LacI-mCherry-GRHL2 protein (Ferrari et al., 2014), respectively (Supplemental Figure S13).

GRHL2 interacted with p300 by the criteria of coimmunoprecipitation of transiently cotransfected genes or of endogenous proteins (Figure 4C). The recombinant proteins interacted only weakly, however (Supplemental Figure S14), suggesting that the interaction is transient or requires posttranslational modifications absent from our recombinant proteins.

**GRHL2 inhibits the C-terminal transactivation domain of p300**

Multiple domains of p300 can coactivate transcription independently. One of these is the C-terminal domain (aa 1665–2414), which interacts with the p160 family of coactivators (Stiehl et al., 2007). Previous reports suggested that the activity of the C-terminal domain is stimulated by autoacetylation catalyzed by the p300 HAT domain (Stiehl et al., 2007). In light of the HAT-inhibitory effect of GRHL2 described above, we hypothesized that GRHL2 inhibited the C-terminal domain through this mechanism. We confirmed that transcriptional activation by the C-terminal domain, assayed as a GAL4-C-term fusion protein, was stimulated by a cotransfected p300 HAT domain and that the latter domain had no detectable ability to activate transcription independently (Figure 5A). GRHL2 inhibited the enhanced transactivation by the p300 C-terminal domain in the presence of cotransfected p300 HAT (Figure 5B). Embedded within the C-terminal domain is a small subdomain called the IRF-3 binding domain (IBID; aa 2050–2096) that mediates the interaction with the p160 coactivator family, including the family member steroid receptor coactivator-1 (SRC-1; Sheppard et al., 2001). Whereas neither the IBID domain of p300 nor SRC-1 alone activated transcription efficiently, the combination of both activated transcription, as reported previously (Figure 5C; Sheppard et al., 2001). GRHL2 potently inhibited transcription that was driven by the complex of p300-IBID and SRC-1 (Figure 5D). Of interest, mutation of the two lysines (K2086 and K2091) of the IBID domain that are acetylated in vivo abrogated the ability of the p300-IBID/SRC1 complex to activate transcription (Figure 5E). These results indicate that the transcriptional activation by the p300 C-terminus, which is supported by SRC-1 and abrogated by GRHL2, depends on acetylation of at least these (and probably other) lysines by p300 HAT or perhaps other GRHL2-sensitive HATs that remain to be determined.

**FIGURE 2:** GRHL2 suppresses the induction of MMP genes and MMP promoters by HGF. (A) GRHL2 suppresses the induction of MMP genes (qPCR analysis; EN, endogenous GRHL2; CE, constitutively expressed GRHL2; KD, GRHL2 shRNA knockdown). (B) GRHL2 suppresses the induction of MMP promoters by HGF. HT1080 cells were cotransfected with either MMP1 or MMP14 promoter-luciferase reporter constructs and GRHL2, E1A, or empty expression vectors. Values represent relative luciferase activity normalized to TK-β-galactosidase control.
A small region of GRHL2 inhibits p300 and is critical for suppressing tubulogenesis and EMT

To identify the region of GRHL2 responsible for p300 inhibition, whole domains of GRHL2 were deleted initially (Figure 6A) and assayed for inhibition of HAT activity and transcriptional activation by GAL4-p300. In light of the lack of GRHL2-binding sites in most GRHL2-repressed promoters (unpublished data), the surprising result was that the DNA-binding domain (aa 245–494) was critical for inhibition (Supplemental Figures S15 and S16). Glutathione S-transferase (GST)-GRHL2 protein subfragments derived from the DNA-binding domain were assayed for HAT inhibition of p300 function and transcriptional activation by GAL4-p300. Consistent with the inability of the GRHL2 Δ425-437 to repress the AP1-dependent promoters MMP1 and MMP14 (Figure 6C), this mutant was unable to suppress HGF-induced tubulogenesis in MDCK cells (Figure 7A). Moreover, wild-type GRHL2 reverses EMT in MSP cells, a cancer stem cell–like subpopulation derived from the mammary epithelial cell line HMLE (Cieply et al., 2012, 2013). The GRHL2 Δ425-437 mutant failed to reverse EMT by the criteria of cell morphology as well as EMT marker protein and mRNA expression (Figure 7B). These results indicated that the inhibition of p300 by GRHL2 contributes significantly to transcriptional reprogramming involved in both tubulogenesis and EMT (Figure 8).

DISCUSSION

Previously we proposed that the epithelial cell is the default phenotype from both development and cancer biological points of view. Under this hypothesis, the epithelial phenotype is adopted automatically by a cell in the absence of genomic/epigenetic alterations or inductive differentiation signaling (Frisch, 1997). Consistent with this idea, E-cadherin–expressing cells are the first to emerge at the late-two-cell stage; these eventually give rise to all differentiated cell types of the adult organism (Hyafil et al., 2008). A GRHL2 Δ425-437 construct (with a synthetic nuclear localization signal) was unable to repress an AP1-promoter, GAL4-p300 transactivation (assayed on a GAL4-Luc reporter), the MMP1 promoter, or the MMP14 promoter (Figure 6D). We recently reported that GRHL2 repressed the expression of the glutamate dehydrogenase-1 gene (GLUD1), with important consequences for metabolism and anoikis (Farris et al., 2016). Of interest, GRHL2 also repressed this promoter in a manner that required a Δ425–437 (Supplemental Figure S17). GRHL2 Δ425-437 was still able to interact, however, with p300 in a cotransfection assay (Supplemental Figure S18).

We hypothesized that the inhibition of p300 function could provide a mechanism for some aspects of transcriptional reprogramming by GRHL2. Consistent with the inhibition of p300 by GRHL2, a Δ425-437 construct (with a synthetic nuclear localization signal) was unable to repress an AP1-promoter, GAL4-p300 transactivation (assayed on a GAL4-Luc reporter), the MMP1 promoter, or the MMP14 promoter (Figure 6D). We recently reported that GRHL2 repressed the expression of the glutamate dehydrogenase-1 gene (GLUD1), with important consequences for metabolism and anoikis (Farris et al., 2016). Of interest, GRHL2 also repressed this promoter in a manner that required a Δ425–437 (Supplemental Figure S17). GRHL2 Δ425-437 was still able to interact, however, with p300 in a cotransfection assay (Supplemental Figure S18).

with p300 IBID domain cooperates with SRC1, a key p300-dependent factor of this developmental process (Yang et al., 1998; Jayaraman et al., 1999; Goel and Janknecht, 2003; Foulds et al., 2004; Lu et al., 2009; Oh et al., 2012; Wolleniek et al., 2012). In addition, the family of p300-dependent TCF/b-catenin transcription complexes is a central hub for Wnt signaling, crucial for nephron induction (Li et al., 2007; Bridgewater et al., 2008; Miller and McCrea, 2010; Ma et al., 2012).

p300 activates transcription through an array of mechanisms: acetylation of histones, acetylation of transcription factors, binding of the p300 bromodomain to acetylated histones to promote transcriptional activity, and recruitment of histone methyltransferases (e.g., Set1b complex; Ogryzko et al., 1996; Gu and Roeder, 1997; Mizzen and Allis, 1998; Ito et al., 2001; Wolf et al., 2002; Stiehl et al., 2007; Chen et al., 2010; Tang et al., 2013). By inhibiting p300 HAT activity, GRHL2 could enforce an inactive state on p300 in at least two ways. First, p300 HAT activity is substantially increased by autoacetylation of an autoinhibitory loop on the HAT domain, which GRHL2 would suppress, stably inhibiting the enzyme (Thompson et al., 2004). Second, the

(Frisch, 1997). Accordingly, we reported previously that GRHL2, shown here to antagonize the coactivator p300, inhibits and reverses the oncogenic EMT, suppressing tumor initiation, drug resistance, and anoikis resistance (Cieply et al., 2012, 2013).

The novel observation that GRHL2 antagonizes p300-dependent pathways in the context of tubulogenesis provides a potentially unifying mechanism for both the developmental and oncologic effects of GRHL2. GRHL2 probably regulates tubulogenesis by additional, p300-independent mechanisms. For example, cells that fail to down-regulate GRHL2 appropriately may fail to down-regulate cell adhesion molecules in response to morphogenetic factors (Werth et al., 2010; Senga et al., 2012). For example, E-cadherin relocalizes from cell junctions to diffuse membrane pattern in protrusive cell extensions during tubulogenesis; this relocalization might be envisioned to require GRHL2 down-regulation and subsequent loss of junctional complex components in these specific cells (Pollack et al., 1998).

p300 contributes to tubulogenesis and cancer-related EMT in multiple important ways, providing a mechanism for GRHL2, via inhibition of p300, to suppress these processes. With regard to cancer, transcription factors that use p300/CBP and additional coactivators that interact with p300/CBP have been implicated in the oncogenic EMT, tumor drug resistance, and tumor recurrence (Matthews et al., 2007; Qin et al., 2009; Santer et al., 2011; Zhou et al., 2012; Delvecchio et al., 2013; Ringel and Wolberger, 2013; Yang et al., 2013; Xu et al., 2014; Cho et al., 2015). The up-regulation of MMPs associated with the oncogenic EMT requires AP-1, Ets, and other p300-dependent factors (Westermanck and Kähäri, 1999; Sun et al., 2004; Chou et al., 2006; Clark et al., 2008; Lee and Partridge, 2010; Santer et al., 2011).

With regard to tubulogenesis, the p300-dependent Ets family transcription factors Etv4 and Etv5 are key transcriptional regulators of this developmental process (Yang et al., 1998; Jayaraman et al., 1999; Goel and Janknecht, 2003; Foulds et al., 2004; Lu et al., 2009; Oh et al., 2012; Wolleniek et al., 2012). In addition, the family of p300-dependent TCF/b-catenin transcription complexes is a central hub for Wnt signaling, crucial for nephron induction (Li et al., 2007; Bridgewater et al., 2008; Miller and McCrea, 2010; Ma et al., 2012).

p300 activates transcription through an array of mechanisms: acetylation of histones, acetylation of transcription factors, binding of the p300 bromodomain to acetylated histones to promote transcriptional activity, and recruitment of histone methyltransferases (e.g., Set1b complex; Ogryzko et al., 1996; Gu and Roeder, 1997; Mizzen and Allis, 1998; Ito et al., 2001; Wolf et al., 2002; Stiehl et al., 2007; Chen et al., 2010; Tang et al., 2013). By inhibiting p300 HAT activity, GRHL2 could enforce an inactive state on p300 in at least two ways. First, p300 HAT activity is substantially increased by autoacetylation of an autoinhibitory loop on the HAT domain, which GRHL2 would suppress, stably inhibiting the enzyme (Thompson et al., 2004). Second, the
extended to critical roles in EMT in contexts such as tubulogenesis and oncogenesis. The inhibition of p300 by GRHL2 provides a mechanism for GRHL2 to enforce the default epithelial phenotype.

MATERIALS AND METHODS

Cell lines

The 293 HEK cells without T antigen (Doug Black, University of California, Los Angeles [UCLA], Los Angeles, CA), MDCK cells (clone M8; Frisch and Francis, 1994), and HT1080 cells (American Type Culture Collection [ATCC], Manassas, VA) were cultured in advanced DMEM (Life Technologies, Carlsbad, CA) with 10% fetal bovine serum (FBS; Hyclone, Chicago, IL) and 1x penicillin-streptomycin-glutamine (PSG) (Invitrogen, Carlsbad, CA). miMCD-3 cells (ATCC) were cultured in advanced DMEM:Ham’s F-12 (Life Technologies) with 10% FBS and 1x PSG. The HMLE and HMLE MSP cells were described previously (Cieply et al., 2013).

Generation of stable cell lines by retroviral transduction and lentiviral transduction

Full-length GRHL2/pMXS-IRES-Puro and retroviral packaging protocol were described previously (Farris et al., 2016). GRHL2 Δ425-437 was subcloned into pMXS-IRES-Puro from GRHL2 Δ425-437-NLS-3xFLAG/pCDNA3.1+. GRHL2 shRNA/pGipZ and scramble control shRNA/pGipZ were obtained from Open Biosystems and packaged as previously described (Cieply et al., 2012). The shRNA construct in pTRIPZ was made by subcloning an MluI-XbaI fragment from pGIPZ.

Cell scattering assays

MDCK cells were plated on collagen-coated six-well dishes to give 25% cell confluency on HGF induction. Cells were treated with 60 ng/ml recombinant human HGF (RD Systems, Minneapolis, MN) in DMEM or fresh DMEM for the time periods indicated. The cells were imaged and then harvested for protein or RNA analysis. Images were obtained using a Zeiss Axiovert 200M, AxioCam MRM camera, Phase 20×/0.55 objective, room temperature, and AxioVision, release 4.8 software. Cell scattering time-lapse movies were taken every 15 min over a 24-h period. Time-lapse images were obtained using a Nikon Eclipse TE2000-E with Photometrics CoolSNAP HQ2 Monochrome charge-coupled device with a Phase 40×/0.75 objective using a Bioptechs Delta T4 Culture Dish Heater, Prior ProScan II Encoded Motorized Stage, and Oko Labs Digital Stage Top Incubator (37°C/5% CO2). For each data point, four 40× images were stitched together using 10% overlap with background correction in NIS-Elements AR (Nikon).

Western blotting

Protein lysates were incubated at 95°C for 5 min in 1x SDS lysis buffer (125 mM Tris-HCl, pH 6.8, 0.04% SDS, 0.024% bromophenol blue, 5% β-mercaptoethanol, and 20% glycerol). SDS–PAGE was run in a 4–20% gradient Novex Tris-glycine gel (Invitrogen). Proteins were electrophoretically transferred to a polyvinylidene difluoride expression constructs. (E) Transactivation by the IBID-SRC-1 complex is contingent upon lysines 2086 and 2091. HT1080 cells were cotransfected with GAL4 response element luciferase reporter I in the presence of the indicated expression constructs. (F) Schematic of p300 domains. Bd, bromodomain; HAT, histone acetyltransferase domain; IBID, IRF-3 binding domain; KIX, CREB-binding domain.

membrane (Immobilon, Waltham, MA) in Tris-glycine buffer with 5% methanol. Membranes were blocked for 1 h in 1× Tris-buffered saline (TBS) plus 5% nonfat milk. Primary and secondary antibodies were incubated in 1× TBS plus 5% nonfat milk plus 0.1% Tween-20. Primary antibodies were incubated for 2 h at room temperature or overnight at 4°C at a 1:1000 dilution. Primary and secondary antibodies were incubated in 1× Tris-buffered saline (TBS) plus 5% nonfat milk plus 0.1% Tween-20. Primary antibodies were incubated for 2 h at room temperature or overnight at 4°C at a 1:1000 dilution. Primary antibodies used were as follows: GRHL2, rabbit (rb); Sigma-Aldrich, St. Louis, MO; β-actin, mouse (ms); Thermo Pierce; fibronectin, ms (BD Biosciences, Franklin Lakes, NJ); vimentin, ms (Santa Cruz Biotechnology, Dallas, TX); β-actin, ms (Sigma-Aldrich); E-cadherin, ms (BD Biosciences); β-catenin, ms (BD Biosciences); glyceraldehyde-3-phosphate dehydrogenase (GAPDH), ms (OriGene, Rockville, MD); acetyl-lysine, rb (Millipore); H3K18AC, rb (Cell Signaling, Danvers, MA); H3K27AC, rb (Cell Signaling); total H3, rb (Cell Signaling); GST, ms (Thermo Pierce, Waltham, MA); p300, rb (sc-584; Santa Cruz Biotechnology); p300, rb (sc-585; Santa Cruz Biotechnology); FLAG, ms (Sigma-Aldrich); and GAL4, rb (Santa Cruz Biotechnology). Goat anti-rabbit or anti-mouse horseradish peroxidase–conjugated secondary antibodies (Bio-Rad) were used at 1:3000 dilution and incubated for 1 h at room temperature RT. Western blot membranes were developed using ECL-West Pico (Pierce) and analyzed using standard chemiluminescence techniques.

**FIGURE 6:** A small region within the DNA-binding domain of GRHL2, aa 425–437, inhibits p300. (A) Schematic of GRHL2 domains. DBD, DNA-binding domain; DD, dimerization domain; TAD, transactivation domain. (B) HAT assays using the indicated GRHL2 fragments, assayed as GST-fusion proteins. (C) GRHL2 aa 425–437 inhibits p300 HAT activity. The indicated fragments derived from GRHL2 were assayed as GST-fusions (left) or recombinant peptides (right) for inhibition of HAT activity. (D) GRHL2 aa 425–437 are required for inhibition of an AP-1 reporter, GAL4 reporter in conjunction with GAL4-p300, MMP1 reporter, or MMP14 reporter. Values represent relative luciferase activity normalized to TK-β-galactosidase control.
(Anders and Huber, 2010) with two independent comparisons: samples with HGF compared with those without or with GRHL2 overexpressed, and samples with HGF compared with those without, both expressing GRHL2 shRNA. Genes were considered differentially expressed if they showed a false discovery rate of ≤0.05 and a fold change of ≥1.5 in either direction. Genes regulated by HGF with shRNA against GRHL2 but not regulated by HGF with GRHL2 overexpressed were uploaded to Ingenuity Pathway Analysis (Qiagen), where a Core Analysis was performed using default settings.

**Quantitative reverse transcription PCR analysis**

MDCK parent, GRHL2/pMXS, and shGRHL2/pGipZ cells were plated on collagen-coated 60-mm² dishes and treated as indicated. Cells were harvested using RNEasy Plus minikit (Qiagen, Hilden, Germany), analyzed using NanoDrop, and converted to cDNA using SuperScript.

**FIGURE 7:** The p300-inhibitory domain of GRHL2 is important for the suppression of tubulogenesis and reversion of EMT. (A) MDCK cells expressing GRHL2 wild-type or GRHL2 Δ425-437 were assayed for tubulogenesis (blue, nuclei; green, actin). Scale bar, 20 μm. Middle, quantitation; right, Western blot confirmation of protein levels. (B) MSP cells expressing GRHL2 wild-type or GRHL2 Δ425-437 were assayed for reversion of EMT by Western blotting for EMT markers (left), cell morphology (middle), or qPCR (right).

**FIGURE 8:** GRHL2 suppresses tubulogenesis and EMT by inhibition of p300.
 Luciferase reporter assays

HT1080 or 293 NOT cells were transiently transfected using Lipofectamine 2000 (Invitrogen) at 1 μg of DNA/3 μl of Lipofectamine. After 20 min of incubation in 300 μl of Opti-MEM (Invitrogen), 1.0 μg DNA was transfected into a 12-well plate with DMEM and refed 4 h later with DMEM. After 28–36 h posttransfection, the cells were washed twice with cold phosphate-buffered saline (PBS), lysed in 200 μl of 1× Cell Culture Lysis Buffer (Promega), frozen for at least 1 h at −80°C, thawed on ice, and centrifuged at 13,200 rpm. The supernatants were assayed for luciferase activity (Promega, Madison, WI) and β-galactosidase activity as internal control (2 μl of empty vector/VR1012 or p300/VR1012) with 6 μl of Lipofectamine empty vector/pCDNA3.1+ or GRHL2-S-TAP/pCDNA3.1+ and 1 μg of RNA. cDNA was analyzed using SYBR Green PCR Master Mix on an Applied Biosystems 7500 Real Time PCR System. Values were determined using the ∆∆CT method using canine CBX1 as internal control. Primers were as follows: CBX1-F (AAG-TATTGCAAGGCACCA, CBX-R (TTTCTTCAATCCAGCCCGC), GRHL2-F (TTCTTCCCCAGGAGAGATG), GRHL2-R (GGCCCAACACACGGAATAAG), MMP1-F (TGACTGAGAAGTCGAC-G), MMP1-R (GACCTTGGAAGAATCAGTT), MMP3-F (CTGGACCCATGCTCTGTA), MMP3-R (GCTTGGAGGATTTGGTTG), MMP13-F (GGACTCCAGGAAGGTGTG), MMP13-R (ATGACACCAGCAATCCGCT), MMP14-F (CCAGAGGAGGCGCATTTTT), MMP14-R (GACTCCCAACCTCTCAATG), MMP1-R (CTGGAGGAACATTCG), FOSL-R (ACACACTCATCGTTTTTG), FOSL1-R (CTTGAACATGGGGATTA), MMP1-F (TGACTGGAAAGGTCGACAGCAG), JUN-F (GACCTTCTACGGACAT), FOSB-R (CACAAACTCCAGACGCTCCT), JUN-F (GACCTTCTACGGACAT), FOSB-F (GGAGAAGAGAAGGGTTCGCC), FOSL1-F (ACACCCTCCCTGACTCCTTT), FOSL1-R (CTTGAACATGGGGATTA), MMP1-R (GACCTTCTACGGACAT), FOS-B (GGAAGAAGAAGGCTTCGCC), FOS-R (CACAAGCTCAGCGGTTCJUN-R (GACCTTCTACGGACAT), FOS-R (CACAAGCTCAGCGGTTCJUN-R (GACCTTCTACGGACAT), JUN-B (GACCTTGGAAGAATCAGTT), JUN-R (GACCTTGGAAGAATCAGTT), JUN-F (GACCTTCTACGGACAT), JUN-B (GACCTTGGAAGAATCAGTT), JUN-F (GACCTTCTACGGACAT), JUN-B (GACCTTGGAAGAATCAGTT), JUN-F (GACCTTCTACGGACAT), JUN-B (GACCTTGGAAGAATCAGTT).

Immunoprecipitation

GRHL2-STAP contained full-length human GRHL2 fused to a C-terminal myc-streptavidin binding peptide (SBP)—S-tag sequence derived by ligating a synthetic oligonucleotide containing the S-tag to a PCR product containing the myc-SBP tags from the pCEM-CTAP vector (Buckstummer et al., 2006). The 293 NOT cells were plated on collagen-coated six-well dishes and transfected using 1 μg of empty vector/pCDNA3.1+ or GRHL2-S-TAP/pCDNA3.1+ and 1 μg of empty vector/VR1012 or p300/VR1012 with 6 μl of Lipofectamine (Invitrogen) in 300 μl of Opti-MEM (Invitrogen). Cells were incubated for 4–6 h with DMEM and then refed with DMEM. At 28 h posttransfection, cells were lysed in 600 μl of cold p300 lysis buffer (25 mM Tris-HCl, pH 8, 75 mM NaCl, 0.5 mM EDTA, 10% glycerol, 0.1% NP-40, and protease inhibitor tablet [Roche, Basel, Switzerland]). Sample lysates were passed through a 1-mL syringe with a 27-gauge needle three times and precipitated for 2 h at 4°C. Lysates were processed using previously described Western blotting methods. For endogenous p300 and exogenous GRHL2, the IBID mutant fragment was digested and ligated into pBIND vector. HA-SRC1/pACTAG was a generous gift from Timothy Beischlag (Simon Fraser University, Burnaby, Canada).

Molecular Biology of the Cell

2488 | P. M. Pfifer et al.
was added and incubated for 90 min. Samples were washed three times in p300 lysis buffer, 45 μl of 2x SDS lysis buffer was added, and samples were heated at 95°C for 5 min. Lysates were processed using previously described Western blotting methods.

**Histone acetylation assays**

Histone acetylation reactions contained indicated amounts of recombinant baculovirus Flag-tagged p300 (37.5 ng; Active Motif, Carlsbad, CA) or baculovirus p300 HAT (1283-1673; Sigma-Aldrich), 250 ng of H3 (Cayman), 100 μM acetyl-CoA (MP Biomedical, Santa Ana, CA), and indicated amounts of PreScission-cleaved GRHL2, GST-GRHL2, or GST alone in 30 μl of p300 acetylation buffer (50 mM Tris-HCl, pH 8.0, 1 mM dithiothreitol [DTT], 0.1 mM EDTA, 10% glycerol, and protease inhibitor). Acetylation reactions were incubated for 15 min at 30°C on heat block. Reactions were diluted with 2x SDS lysis buffer and incubated for 5 min at 95°C. Lysates were processed using previously described Western blotting methods.

**Recombinant protein purification**

Full-length GRHL2 was subcloned into pGEX-6P-3 vector (GE Healthcare) and transformed into BL21 bacteria (Invitrogen). GRHL2 fragments were subcloned into pGEX-6p-3 using BamHI and SalI. A colony was selected and grown in 20 ml of LB+amp overnight at 37°C. The next day, 10 ml of culture was inoculated into 500 ml of LB+amp and incubated for ~2 h at 37°C with shaking until OD ~ 0.6 was obtained. Isopropyl-β-D-thiogalactosidase was added to final concentration of 0.1 mM and incubated overnight on a shaker at room temperature. The bacteria were spun in a chilled centrifuge for 10 min at 5000 rpm. Bacterial pellet was resuspended in 10 ml of BL21 lysis buffer (1× PBS, 1% Triton-100, 1 mM DTT, 0.4% lysozyme, and protease inhibitor tablet), incubated for 10 min, and sonicated twice for 30 s. The suspension was cleared at 13,000 rpm for 10 min. A 150-μl amount of 50% glutathione-Sepharose beads (GE Healthcare, Little Chalfont, United Kingdom) was added to the supernatant, which was incubated for 2 h with rotation at 4°C. Glutathione-Sepharose beads were washed three times with glutathione washing buffer (1× PBS, 1 mM DTT, and 0.1% Triton-X) and eluted for 30 min with glutathione elution buffer (100 mM Tris, pH 8, 150 mM NaCl, 20 mM glutathione, and protease inhibitors). Alternatively, glutathione-Sepharose beads with GRHL2 protein attached were washed three times in PreScission cleavage buffer (50 mM Tris-HCl, 150 mM NaCl, 1 mM EDTA, 1 mM DTT, pH 7.0). The GST-GRHL2 on glutathione-Sepharose beads was cleaved by adding 80 μl of PreScission Protease (GE Healthcare) per milliliter of PreScission cleavage buffer at 5°C overnight. The sample was spun at 2000 rpm, and the supernatant with the GST-cleaved GRHL2 was obtained. Proteins were dialyzed against p300 acetylation buffer overnight at 4°C using a 20,000 MWCO Slide-A-Lyzer MINI Dialysis Unit (Thermo Scientific). Protein was analyzed on SDS–PAGE by Coomassie blue staining and quantified by comparison of Coomassie staining to a BSA standard and/or a bicinchoninic acid assay. Synthetic peptides were purchased from Thermo Fisher Scientific with N-terminus acetyl group and C-terminus amidation: GRHL2 aa 420–442 (GAERKIRD-EERQNRKKGKGQAS) and scramble (IDEKNGKRERQKR).

Chromatin immunoprecipitation

For ChIP assay, HT1080 cell lines expressing empty vector/pMXS or GRHL2/pMXS cells were used and chromatin generated as described previously, with the following modifications (Kumar et al., 2011): 1) Immunoprecipitation was performed with 3 μg of H3K27-Ac anti-body (Cell Signaling) or rabbit IgG (Jackson) to 3.3 × 10⁶ cell equivalents in ChIP RIPA buffer. 2) Protein A-Sepharose was used instead of FLAG-agarose beads. 3) qPCR was performed using 2× SYBR Green Master Mix (10 μl; Applied Biosystems, Foster City, CA), 0.08 μl of 100 mM primer, and 1 μl of ChIP DNA in a 20-μl reaction. Primer sequences were as follows: MMP1-1-F (AACCTCAGAAAGCCCGAACAG), MMP1-1-R (TACTAAGCTGGACACCTGA), MMP1-2-F (CAGATGCTGTGGTGATGATGA), MMP1-2-R (TGCTTCGACTGTTGCC), MMP1-4-F (AAGTAAGTGGATCCTCGGCGC), MMP1-4-R (GGAGTTGCTCCCCGGTTGAA), MMP2-2-F (TGCCCATCATCAGTTCCTCC), MMP2-2-R (CCCCCAAGCTGTTACCAGAAG), ZEB1-1-F (GGCGACGCCGGCTAGTGCG), ZEB1-1-R (AAAGTGGAGGCCTGGCGGC), ZEB1-2-F (CTGCAAGGGCCATAGCGCT), ZEB1-2-R (TTCCGGTTCCAGGCCCTCT), CHD1-F (ACTCCAGGCTAGGATTCC), CHD1-R (CGCGAAGCTCACAGCTTGGCT), ESPR1-F (GGGAGCTTGTCAAGTCAAC), ESPR1-R (TCTAAAATCCGGGCAACGCA), RAB25-F (AGGTCTCTGGCTTTCTCC), RAB25-R (TTGGGGTTAGGGACTCTT), GAPDH-F (ATGTTGCGACTGCTTGG), and GAPDH-R (TGGCCAGAAGCTTGGGAAA). Results were normalized to GAPDH values.

Ex vivo kidney culture

All experiments involving mice were approved by the West Virginia University Institutional Animal Care and Use Committee. Hoech3/EGFP transgenic mice and the ex vivo kidney culture method were described previously (Zhao et al., 2004). We removed embryonic kidney at embryonic day 13.5 and cultured the kidneys in 1 μM batimatast (Tocris, Bristol, United Kingdom) or vector in culture medium for 48 h. Images were taken of GFP ureteric buds on an Olympus MVX10 Macro Zoom, ORCA-Flash 4.0 Monochrome camera, objective 2x, zoom 4x, fluorescein isothiocyanate, and using CellSen Imaging Software. Ureteric buds were counted for quantification.

Confocal microscopy of transfected RRE.1 cells

RRE.1 cells, wild-type e1a-NLS-LacI-Cherry, and empty vector NLS-LacI-mCherry were generous gifts from Arnold Berk, and the experiment was performed as previously described (Verschure et al., 2005; Ferrari et al., 2014). GRHL2 was subcloned into empty vector NLS-LacI-mCherry using SalI. Images were taken on a Zeiss Axioimager Z1 microscope, LSM 510 confocal, 63×/0.75 LDPlan-Neofluar, 4′,6-diamidino-2-phenylindole and rhodamine, and Zeiss Zen software. Images were quantified using mean area on ImageJ (National Institutes of Health, Bethesda, MD).

Statistical analysis

Error bars in graphs represent SD. p values were calculated using a Student’s two-tailed t test.
