Minimalistic supramolecular proteoglycan mimics by co-assembly of aromatic peptide and carbohydrate amphiphiles†

Alexandra Brito,‡‡‡ Yucef M. Abul-Haija,‡‡‡ Diana Soares da Costa,§‡§ Ricardo A. Pires,‡‡‡‡¶¶ and Iva Pashkuleva‡‡‡

We report the co-assembly of aromatic carbohydrate and dipetide amphiphiles under physiological conditions as a strategy to generate minimalistic proteoglycan mimics. The resulting nanofibers present a structural, fluorenylmethoxycarbonyl-diphenylalanine (Fmoc-FF) core and a functional carbohydrate (Fmoc-glucosamine-6-sulfate or -phosphate) shell. The size, degree of bundling and mechanical properties of the assembled structures depend on the chemical nature of the carbohydrate amphiphile used. In cell culture medium, these nanofibers can further organize into supramolecular hydrogels. We demonstrate that, similar to proteoglycans, the assembled gels prolong the stability of growth factors and preserve the viability of cultured cells. Our results demonstrate that this approach can be applied to the design of extracellular matrix (ECM) substitutes for future regenerative therapies.

Introduction

Molecular self-assembly is a versatile bottom-up approach for the design and synthesis of functional biomaterials.1–5 The main advantage of this approach is the possibility to create structural and functional biomimetics with simple and systematically customizable compositions.5–7 As an example, bioactive peptide amphiphiles (PA) of varying complexity have been used as simple functional analogues of various proteins.2–4

These building blocks can code specific biochemical information and transfer it to the surrounding (biological) environment. Glycosylation, the process of functional decoration of proteins with carbohydrate chains, is the most common post-translational modification that diversifies the roles of proteins by instructing their folding and by activating specific recognition events and different signalling pathways.6 Attached carbohydrate chains can also have a protective role which contributes to the stability and activity of proteins.6,7 So far, these diverse roles of carbohydrates have received little attention, compared to peptides, in the design of molecular self-assembling blocks for the synthesis of functional supramolecular gels.8–14

Aiming to develop extracellular matrix (ECM) mimics, recent studies introduced the use of peptide amphiphiles (PAs) end-on functionalized with carbohydrate moieties.8–11 Upon assembly of such amphiphiles, the carbohydrate units are exposed on the surface of the assembled fibre and are able to participate in multivalent biospecific interactions. While this approach seems straightforward for generating supramolecular mimics of proteoglycans, the introduction of the carbohydrate unit is challenging in terms of PA synthesis and assembly as it may disturb the delicate balance of forces governing the process of self-organization.15,16

Multicomponent co-assembly offers a possibility to expand the chemical diversity and functional complexity of supramolecular systems without compromising the simplicity of the building blocks.17 The feasibility of this approach has been demonstrated by a combination of different PAs.15–18 We hypothesized that a similar strategy can also be applied for co-assembly of simple carbohydrate amphiphiles (CAs, 1) and their
peptide analogues (2) and the result will be a synergistic modular system mimicking proteoglycans (Scheme 1).

The range of carbohydrates found in biological systems provide a rich library of water soluble, chiral building blocks. Simple carbohydrate amphiphiles (CAs) functionalized with aromatic moieties such as naphthalene and fluorenylmethoxycarbonyl (Fmoc) have been recently developed and shown to form self-assembled structures. However, the amphiphiles bearing the naphthalene unit do not form gels and the ones functionalized with Fmoc require a heating–cooling cycle or a specific enzymatic stimulus to enable the formation of gels under physiological conditions.

Herein, we describe bi-component systems, in which fluorenylmethoxycarbonyl-diphenylalanine (Fmoc-FF) provides the structural component, while Fmoc-carbohydrate is the solvent-exposed functional element, which can be systematically exchanged (Scheme 1). We demonstrate that these modular materials combine the simplicity of small molecules with the versatility and biofunctionality of glycans and proteins, respectively.

Results and discussion

Self-assembly of aromatic carbohydrate amphiphiles (1) and Fmoc-FF (2)

The amphiphiles Fmoc-glucosamine-6-sulfate (GlcN6S, 1b) and Fmoc-glucosamine-6-phosphate (Fmoc-GlcN6P, 1c) were obtained from the respective glucosamines in a single-step reaction using an excess of Fmoc chloride (details on the synthesis and chemical characterization of the amphiphiles are provided in the ESI, Fig. S1–S13†).

Fmoc-GlcN (1a) is not soluble in water at room temperature. Upon temperature rising (80 °C), it dissolves and organizes spontaneously into nanofibers that, at room temperature, form a highly hydrated scaffold (Fig. 1A). On the other hand, Fmoc-FF (2) dissolves in water only at basic pH (~11) and self-assembles upon pH decrease. The assembly of 2 is controlled by peptidic hydrogen bonds that result in the formation of β-sheet-like structures that are further stabilized by aromatic π–π interactions, whilst the organization of 1a is driven by a combination of CH–π and π–π (T-shape) stacking interactions.

We compared the properties of the formed assemblies by AFM (Fig. 1B and C, black outlines) and found that the fibres have a similar size but their Young’s moduli are significantly different: the PA 2 assemblies in very rigid fibres (~16 GPa) that have a 4-fold higher modulus than the ones obtained from the carbohydrate analogue 1a (~4 GPa).
The co-assembly of 2 and 1a is challenging as both compounds have limited solubility in water and dissolve under different conditions. We functionalized 1a with polar groups aiming to improve the solubility and to impart relevant functional groups. The co-assembled 1b and 1c have intermediate mechanical properties when compared with the PA and CA single component fibres. FTIR spectroscopy was also performed to characterize the co-assemblies (Fig. 1E). Absorptions at 1625 and 1687 cm\(^{-1}\) are associated with the formation of H-bonding by Fmoc-peptide amide and carbamate groups. As expected, these peaks are missing in the spectra of CA (1b and 1c) solutions. On the other hand, the amide I peaks are clearly observed for the co-assembled systems (2/1b and 2/1c) demonstrating that the β-sheet structure remains intact in the presence of the CA although the lower intensity of these peaks suggests that a degree of intercalation might have occurred.

Previously, different models for assembly of two-component systems have been proposed. Our results (AFM; CD and FTIR spectra) indicate that 2 co-assembles with 1b and 1c into core–shell nanofibers with the carbohydrate moieties exposed on the surface. Such co-assembly would involve intercalation between the Fmoc moieties of the CA and PA on the formed fibre surface (Scheme 1B), thus shielding the hydrophobic Fmoc while exposing the carbohydrate unit. We studied the surface charge of the formed nanofibers in order to confirm this organization (Table S1i). The value determined for 2 was \(-0.04\) mV, which agrees with our previous work showing that the apparent \(pK_a\) of the terminal carboxylic acid in 2 is substantially shifted due to the favoured self-assembly of the uncharged form.

The co-assembled systems 2/1b and 2/1c have negative zeta potentials, \(-56.0 \pm 1.5\) mV and \(-55.4 \pm 6.1\) mV respectively. As expected, the absolute values are smaller than the ones of the precursor CAs due to the lower density of the functional groups on the co-assembled fibres as compared with the single component micelles. These results further confirm our hypothesis for co-assembly resulting in the formation of systems with a peptide-based core and carbohydrate shell.

Characterization of the supramolecular gels

Upon contact with cell culture medium (pH 7.4), the PA 2 and its co-assemblies with the CAs form self-sustained macroscopic gels (Fig. 2A).

We used AFM to analyse the gels and observed a typical entangled fibrous network for all studied compositions (Fig. 2B and S21†). However, two major differences can be observed in the AFM images: fibres of 2 are thinner and more entangled compared to the ones generated by co-assembly (2/1b and 2/1c). These differences are also reflected in the viscoelastic properties of the gels: mixed systems form more robust gels in all studied media (Fig. 2C and S23†). Previous studies have demonstrated that gelation of similar PA systems can be either pH- or salt-triggered via the formation of salt bridges between the anions exposed on the fibre surface (Scheme 1C). Our rheological studies confirmed that these stabilizing interactions are also present in our current system: upon reduction of the pH by adding Dulbecco’s Phosphate-Buffered Saline (DPBS, pH 7.4, only monovalent cations), we observed the formation of soft gels. The moduli of the formed gels increased significantly in the presence of divalent Ca\(^{2+}\) ions (Fig. 2C, DPBS + CaCl\(_2\)). This difference depends on the anions exposed on the fibre surface and we observed the following order HPO\(_4^{2-}\)/H\(_2\)PO\(_4^-\) (2/1e 3-fold increase) > SO\(_4^{2-}\) (2/1b, 3-fold increase) > COO\(^-\) (2, 2.7-fold increase).
Interactions of the supramolecular gels with basic fibroblast growth factors (FGF-2)

Basic fibroblast growth factor (FGF-2) is a glycoprotein that has a pleiotropic effect in different tissues and organs: it is crucial for processes such as angiogenesis, development, wound healing, cell survival and differentiation, among others.\textsuperscript{15,16} It is also known for its thermal instability: it loses most of its activity after 24 h of incubation at 37 °C (Fig. S24†).\textsuperscript{37} In its native environment – the pericellular space – FGF-2 interacts specifically with cell surface proteoglycans, which protect it from degradation and aggregation.\textsuperscript{6} Electrostatic interactions and hydrogen bonding are the main driving forces for the formation of proteoglycan-FGF-2 complexes.\textsuperscript{36,38} Proteoglycan charge density is crucial for these interactions as basic amino acid residues in the growth factor, usually ordered in Cardin–Weintraub sequences, are the main contributors to the formation of the complexes.\textsuperscript{6,38} Indeed, addition of heparin (the most negatively charged natural biomolecule) or heparan sulphate to the FGF-2 incubation media prolongs its activity.\textsuperscript{37,39,40} We therefore tested the developed systems for their capacity to protect FGF-2 and preserve its bioactivity under physiological conditions (Fig. 3).\textsuperscript{9}

We added the growth factor into the gels (details are provided in the ESI†) and the successful encapsulation was confirmed by immunostaining and SDS-PAGE (Fig. 3, 0D). Of note, immunostaining allows visualisation only of active FGF-2 as it is based on the recognition of the growth factor by a specific antibody with a fluorescent tag. The gels with the encapsulated growth factor were maintained under standard cell culture conditions (DMEM at 37 °C) for 7 days and then characterised again (Fig. 3, 7D). Our results demonstrated that mixed systems (2/1b and 2/1c) protect better the FGF-2 from degradation when compared to the non-functionalized peptide nanofibers (2); stronger co-localization (Fig. 3A) and more protein (Fig. 3B) are visible for the FGF-2 loaded in the co-assembled gels after 7 days. Moreover, ELISA tests did not show any release of the growth factor to the surrounding media for this period of time. These results indicate that FGF-2 is simply entrapped in the Fmoc-FF gel and thus, attainable for degradation (although slower as compared with free FGF-2). On the other hand, in the mixed systems, FGF-2 interacts with the carbohydrates exposed on the fiber surface, thus copyscating the natural proteoglycan protection mechanism.

Cytotoxicity of the supramolecular gels

Next, we tested the ability of the gels to support viable cells. Initially, we used i.929 cells that are recommended for standard \textit{in vitro} cytotoxicity tests. Our results demonstrate that cells remain viable either when they are seeded on top of the gels
Fig. 4 Live/dead assays for L929 cultured (A) on top of the gels or (B) encapsulated within the gels for 48 h. Dulbecco's Modified Eagle's Medium (DMEM) was used for these tests.

(Fig. 4A and S27†) or when they are encapsulated inside the gels (Fig. 4B and S27†). Chondrogenic cell line ATDC5 (Fig. S25†) and epithelial HeLa cells (Fig. S26†) were also tested with the assembled materials to prove their versatility. In all the cases, we observed a majority of viable cells (Fig. S27†). The culture of these cell lines requires the use of media supplemented with proteins (10% fetal bovine serum, FBS) that can affect the mechanical properties of the gels.† Our results demonstrated that indeed the presence of proteins affects significantly the storage moduli of the gels: when DPBS supplemented with CaCl₂ was replaced with DMEM (the same Ca²⁺ concentration) supplemented with FBS we observed a significant decrease of the storage moduli, especially for the co-assembled systems (Fig. 2C and S23†). Of note, the substitution of DMEM with DMEM/F12 does not induce any significant change in the mechanical properties of the gels (Fig. S23†). These data suggest that the proteins from the medium interact with the mixed systems and disrupt partially the ionic crosslinking bridges between different nanofiber segments. As the mechanical properties of the assembled gels under cell culture conditions are very similar, we suggest that the observed different number of adherent/encapsulated cells is due to the different chemistry of the generated supramolecular systems and their specific interactions with the cultured cells.

Conclusions

We have successfully designed and synthesized supramolecular, functional glycoprotein mimics by co-assembly of simple building blocks. In addition to the simplicity of the building blocks, the proposed approach has several other advantages: the assembly is carried out under physiological conditions, and the formed hydrogels are stable, non-cytotoxic and biofunctional. We also demonstrated that by changing the chemical design in a systematic way we are able to control the biofunctionality and mechanical properties of the supramolecular gels – features that are of key importance in the design of materials for biomedical and tissue engineering applications.
